Determination of Equilibrium Constant at Supercritical Carbon Dioxide Condition for Pithecellobium Jiringan (Jack) Prain Seeds.
Mohd Azizi Che Yunus, Nur Husnina Arsad, Zuhaili Idham

Abstract—Pithecellobium Jiringan (Jack) Prain (P.Jiringan) is one of the medicinal plant sources that consist of antioxidant compounds. The aim of this study was to investigate the effects of supercritical carbon dioxide (SC-CO₂) extraction parameters on solubility and to determine the equilibrium constant of P.Jiringan oil in SC-CO₂ and correlated the data with Chrastil and del Valle & Aguilera models. The experimental were conducted at temperatures ranging from 40 °C to 70 °C and pressure from 27.58 MPa to 44.82 MPa. The extraction duration was 60 minutes. The result shows the solubility of oil increased as the density of CO₂ increased at constant temperature. The solubility experimental data correlated with both model was good agreement with more that 95% similarity where the Chrastil model was the best model correlated with the experimental data since the AARD% of Chrastil model (0.206%) is lowest compared to AARD% of del Valle and Aguilera model (0.5818). In addition, SC-CO₂ give the highest oil yields compared to accelerated solvent extraction (ASE) and soxhlet extraction process.

Keywords: Equilibrium constant, Chrastil’s model, Pithecellobium Jiringan (Jack) Prain, Solubility, Supercritical fluid extraction

I. Introduction

Supercritical carbon dioxide extraction (SC-CO₂) is the most commonly use for supercritical fluid extraction (SFE) application because of its moderate critical temperature and pressure of 31° and 7.38MPa SFE is known to be dependent on the density of the fluid that in turn can be manipulated through control of the system pressure and temperature. The dissolving power of a SFE increases with isothermal increase in density.

The basic principle of SFE is that the solubility of a interest solute in a solvent varies with both temperature and pressure. At ambient conditions (25 °C and 1 bar) the solubility of a solute in a gas is usually related directly to the vapor pressure of the solute and is generally negligible. Moreover, one of the main advantages of supercritical fluids is the ability to modify their selectivity by varying the pressure and temperature (modify fluid density). Therefore, supercritical fluids are often used to extract selectively or separate specific compounds from a mixture. On the other hand, accelerated solvent extraction (ASE) and soxhlet extraction were used to make a comparison with SC-CO₂ on the global oil yield. The comparison was study to determine the best process to extract oil from P.Jiringan seeds.

Malaysia has about 12,000 species of plants of which about 1,300 are said to be medicinal and only a small number of these plants have been fully investigated for their potential [1]. One of them is Pithecellobium Jiringan (Jack) Prain (P.Jiringan). The beans are commercially available in markets during most of the year and even though the P.Jiringan seeds, it is rich in essential compounds including protein, carbohydrates, fiber, calcium, phosphorus, vitamins and sterols which make it possible to be developed into medicinal drugs especially for anti-diabetics and anti-hypertension [2,3].

Solubility measurement can be obtained both experimental and modeling. It is important to obtain the solubility of solutes in the SC-CO₂ extraction in order to determine the optimal operating conditions. Moreover, the solubility model also very significant in up scaling process. Most models can be classified as being either semi-empirical or equation-of-state based. However, semi-empirical models are often utilized because their relative ease of application equated to equations of state. The most common semi-empirical models are established upon providing a correlation between solubility and density; hence, they are referred to as density-based models. The most common semi-empirical methods are those developed by Chrastil [4]. This study, focus more on correlating the solubility of some compounds in SC-CO₂ using Chrastil’s model and del Valle and Aguilera model [5]. The aim of this study was to investigate the effects of extraction conditions namely, pressure and temperature especially on the solubility of P.Jiringan oil in SC-CO₂, besides extraction yield. Furthermore, the correlation of experimental solubility data correlated with Chrastil and del Valle and Aguilera models were in this study.

II. Materials and Methods

A. Sample Preparation

Matured and fresh P.Jiringan seeds were used and obtained from a local market at Taman Universiti, Skudai, Malaysia. Seeds was separated from fruits and thoroughly washed with tap water followed by distilled water. Next, the seeds were cut into small pieces (2-3 cm diameter and 1mm thickness) and were sun-dry conventionally all day long. P.Jiringan seeds were finely ground achieved powder form. The particle size was determined by sieving and was fixed at 215 μm. 215 μm was the best particle size to obtain the maximum yield [2].
B Supercritical Carbon Dioxide System

Supercritical fluid extraction was performed using SFX TM 220 extraction system (ISCO, Lincoln, NE, US) consisting of high pressure syringe pump (Model: 100DX), extractor chamber, 2.5 mL stainless steel extraction cell and extractor controller (Model: SFX 200) was used in this study. Others part involved were a chiller (Model: Yih Der BL-730), CO₂ with 99.99% purity (MOX Gases Sdn. Bhd. Selangor) was used as a solvent throughout the process.

The ranges of parameters were presented in Table 1. On the other hand, the fixed parameters for particle size, mass of sample, flow rate and extraction time were 215 μm, 2.0 g, 2.2 mL/min and 60 minutes respectively.

C Soxhlet Extraction

Soxhlet extractions were performed using 15 g weighed of powdered P.Jiringan seeds and were placed in a thimble holder. Soxhlet extraction was carried out using 300 mL of solvents (Hexane and Water). The extraction time was performed in 6 hours.

D Accelerated Solvent Extraction (ASE)

10 g of grounded P. Jiringan seeds were extracted using ASE 150 system (Dionex, Sunnyvale, CA, USA) with hexane as a solvent. Extractions were performed at three different parameters which are temperatures (70, 90 and 110 ºC), extraction times (5, 10 and 15 minutes) and cycles (1, 2 and 3). Sample mixed homogeneously with 5 g weight of diatomaceous earth was loaded into 34 mL stainless-steel extraction cells and filled with solvent up to a pressure of 1500 psi.

E Solubility of P.Jiringan oil in SC-CO₂

In the experimental work, the solubility data of P.Jiringan oil in supercritical CO₂ for temperatures ranges from 40 ºC to 70 ºC and pressures ranges from 27.58 MPa to 44.82 MPa were measured by plotting experimental data of mass of oil extracted against the mass of CO₂ used (overall extraction curves). The curves were developed at 2.2 mL/min of CO₂ flow rate. Therefore, the solubility (y*) was the slope of the constant extraction rate period of the overall extraction curves. Chrastil and Del Valle & Aguilera models were selected to evaluate the use of empirical model to correlate solubility data of P.Jiringan oil in supercritical CO₂. These models are described to be appropriate for the range of temperature and pressure from which the experimental values were obtained.

A multilinear regression was performed by using Solver in Excel 2007 program to determine the model constants. The accuracy of Chrastil models and del Valle and Aguilera model were quantified by analysis of average absolute relative deviation percentage (AARD%). Equation 1 represents the method in calculating AARD%.

\[ AARD% = \frac{100}{n} \sum_{i=1}^{n} \left( \frac{Y_{i,\text{exp}} - Y_{i,\text{calc}}}{Y_{i,\text{exp}}} \right) \times 100 \]  

Where n = number of data

\[ Y_{i,\text{exp}} = \text{solubility data obtained from experimental respectively at } i^{th} \text{ condition} \]

\[ Y_{i,\text{calc}} = \text{solubility data obtained from Chrastil model respectively at } i^{th} \text{ condition} \]

F Chrastil Model

The Chrastil’s model studies the formation of a solvation complex between the solvent and the solute molecules in the equilibrium, establishing a linear relation between solubility, solvent density and process temperature. The equation that represents the solubility model derived by Chrastil showed as follows:

\[ Y^* = \rho^a \exp (-\Delta a_\rho + b) \]  

\[ \frac{1}{T} \]

Where \( y^* \) = the solute solubility

\[ T = \text{temperature (K)} \]

\[ \rho = \text{solvent density (g/L)} \]

Meanwhile, for coefficient of a and b represents:

\[ a = \frac{\Delta H}{RT} \]

\[ b = \ln (M_A + kM_B) + q - k \ln M_B \]

Where; \( \Delta H = \Delta H_{\text{solv}} + \Delta H_{\text{vap}} \) and \( q = q_s + q_v \)

\[ M_A = \text{molecular weights of the solute} \]

\[ M_B = \text{molecular weights of the gas} \]

Also, a, b and k represent the adjustable constants of the model. The constant k indicates the number of CO₂ molecules present in the complex solute-solvent (equilibrium constant). The a and b parameters are vaporizing enthalpy and molecular weight dependants, respectively.

G Del Valle & Aguilera’s Model

The del Valle and Aguilera model is a modification of the Chrastil model. The equation of del Valle and Aguilera model can be expressed as follows:

\[ \ln y^* = k \ln \rho + a + b + c \frac{1}{T} - \frac{1}{T^2} \]  

Where \( k, a, b \) and \( c \) are adjustable constants.
III. Results and Discussion

A Solubility of P. jiringan Oil in SC-CO₂

The solubility of P. jiringan oil in SC-CO₂ was evaluated at temperatures ranging from 40 °C to 70 °C and pressures ranging from 27.58 MPa to 44.82 MPa. The solubility data was obtained using a dynamic method and overall extraction curves were plotted as mass of carbon dioxide used versus mass of oil extracted. The solubility data for each condition were obtained from the slope of the linear portion of the overall extraction curve.

Figure 1 shows the effects of pressure and temperature on the solubility of P. jiringan oil in SC-CO₂. The result shows that at constant temperature, the solubility of oil increased as the density of CO₂ increased. Meanwhile, at constant pressure, the solubility of oil increased as the temperature increased even though the density of CO₂ decreased. From the observation, it showed that as the pressure increased from 27.58 MPa to 31.03 MPa, the solubility increased drastically at temperature 60 °C and 70 °C. However, the solubility was slightly increased at the temperatures of 40 °C and 50 °C. This was due to the competing effect where the increase in vapor pressure was more dominant than the decrease of CO₂ density.

A similar result studied on the effects of pressure and temperature on the solubility of P. jiringan oil in SC-CO₂ had been reported [2]. The parameters used in his study were pressures at the range of 20.68 MPa to 55.15 MPa and temperatures at 40 °C, 50 °C, 60 °C, 70 °C and 80 °C. The result showed that the solubility increased at a constant pressure. Moreover, the solubility effect as a function of pressure was less significant compared to the solubility effect as a function of temperature. The solubility in his study increased from 1.10 to 2.60 mg oil per g CO₂ at the constant pressure of 55.15 MPa as the temperature increased from 40 °C to 80 °C. It shows that the effect of temperature was more dominant than the pressure.

This trend was similarly reported by Ana Najwa [6] findings which showed the increment of solubility where the increase in pressure was slower than as the increase in temperature. Besides that, the solubility of palm oil in R134a at 60 °C and 80 °C suddenly increased from 45 to 60 bar. This is due to the balancing between the increase in the solute vapor pressure and the decrease in solvent density which is known as competing effect. This phenomenon occurred at the lowest and the highest temperature. In her study, she assumed that the solute vapor pressure played a major role in increasing the oil solubility and she concluded that temperature had a dominant effect on palm oil solubility.

The solubility data of P. jiringan oil in SC-CO₂ in this study were correlated with models proposed by Chrastil (Equation 2) and by Del Valle and Aguilera (Equation 3). Figure 2 shows the correlation of solubility experimental data of P. jiringan oil solubility in SC-CO₂ by chrastil model and by del Valle and Aguilera model.

In this analysis, the experimental data was accommodated with both models to obtain the parameters involved. The parameters of Chrastil’s model (a, b and k) and del Valle and Aguilera model (a, b, c and k) were determined by minimizing the objective function (Equation 1) which was known as average absolute relative deviation percentage (AARD%) using Solver in Excel 2007 program.

In Chrastil’s model, the parameters obtained represent the important term. For parameter a, it represents the heat of salvation and vaporization of the solute, meanwhile parameter b represents the molecular weight and melting point of solute involved and k represents the average number of molecules that form the solvate-complex which is also known as equilibrium constant. From the analysis of the results, the AARD% of correlation between the solubility experimental data with the Chrastil’s model obtained was 0.206%.

Moreover, in del Valle and Aguilera model, the parameters used were the same as Chrastil’s model and c was the additional constant for the model. The analysis was done by minimizing the AARD% and directly determined the constant parameters which were a, b, c and k in the equation. The results from the analysis show that the AARD% of correlation between the solubility experimental data with the del Valle and Aguilera model obtained was 0.5818%.

Constant parameter of a showed the influence of the temperature change inside the extraction vessel. According to Maria Salud [7] as an absolute value of parameter a is high, it relates with high temperature influence. Moreover, they said that lower k value indicates that most of the oil was extracted with SC-CO₂ from the sample itself. Meanwhile, constant parameter b indicates that the solute had been extracted. In addition, according to Wahyu B. Sentianto [8], parameter k and b can be assumed as parameters that are independent of temperature. Following this, the solubility parameters a, b, c and k of Chrastil and del Valle-Aguilera model calculated are shown in Table 2.
Previous researchers had reported the solubility correlation by Chrastil’s model and by del Valle and Aguilera model in literature. The Chrastil model and del Valle-Aguilera model were used to correlate solubility data of virgin coconut oil (VCO) in CO₂ at temperature ranges of 40 °C to 80 °C and pressure ranges of 20.7 MPa to 34.5 MPa. The result shows that AARD% of del Valle and Aguilera model obtained was 0.39% meanwhile, AARD% of Chrastil model obtained was 0.93%. Even though both models gave good correlation of the data, he conclude that del Valle and Aguilera model as the best model correlated with the experimental data since the AARD% of del Valle and Aguilera model is lowest compared to AARD% of chrastil model [9].

The results show that most of the data obtained from Chrastil model approaching nearly to the solubility of experimental data compared to data obtained from del Valle and Aguilera model. Therefore, it shows that the Chrastil model was successful matched to the solubility experimental data compared to del Valle and Aguilera model.

In addition, the value of AARD% of Chrastil’s and del Valle and Aguilera models was used as a comparison. The result of AARD% calculated for Chrastil model and del Valle and Aguilera model are shown in Table 3. The AARD% from del Valle-Aguilera model was poor compared to the value from Chrastil model. The best model that fitted the experimental data was obtained by Chrastil model (Equation 2) with the smallest AARD% value.

### IV. Conclusion

The extraction of P. Jiringan seeds using supercritical carbon dioxide extraction was performed at temperatures ranging from 40°C to 70°C and pressures ranging from 27.58MPa to 44.82MPa. The solubility of P. Jiringan oil in supercritical carbon dioxide was measured from the slope of the linear portion of the overall extraction curve. The results show that at constant temperature, the solubility of P. Jiringan oil increased as the density of CO₂ increased. In the meantime, at constant pressure, the solubility of oil increased as the temperature increased even though the density of CO₂ decreased. The maximum solubility of P. Jiringan oil was 2.0462 mg oil per g of CO₂ obtained at the temperature of 70°C and the pressure of 44.82MPa. On the other hand, the minimum solubility of P. Jiringan oil was 0.3394 mg oil per g of CO₂ obtained at the lowest supercritical condition which was at the temperature of 40°C and the pressure of 27.58MPa.

The experimental solubility data was correlated with two different empirical equations proposed correspondingly by Chrastil and del Valle and Aguilera. The lowest deviation between the experimental data and correlated values was obtained from the results taken at 60°C and 37.92MPa using the Chrastil model. From the observation, the solubility data were successfully fitted to the Chrastil model compared to del Valle and Aguilera model based on the AARD% value. The AARD% of Chrastil model which was 0.206% was lower than AARD% of del Valle and Aguilera model which was 0.5818%. In conclusion, the equilibrium constant for P. Jiringan seeds obtained was 7.74925.
