Viscoelastic Kirchhoff Plate Analysis via Mixed Finite Element Formulation

Fethi Kadioğlu and Gülçin Tekin

Abstract—In this study, a functional for the dynamic analysis of viscoelastic Kirchhoff plates is obtained through an efficient systematic procedure based on the Gâteaux Differential Method. For the solution of the derived functional, mixed finite element method in transformed Laplace-Carson space is used. In this functional, there exists four independent variables such as deflection \( w \), internal forces \( (M_x, M_y, M_{xy}) \) in addition to the dynamic and geometric boundary condition terms. For modeling the viscoelastic behavior, four parameter solid model is employed. For transformation of the solutions obtained in the Laplace-Carson domain to the time domain, different numerical inverse transform techniques are employed. The developed solution technique is applied to several dynamic example problems for the verification of the suggested numerical procedure.

Keywords—dynamic analysis, viscoelastic plates, Gâteaux differential, mixed finite element method, Laplace-Carson transform

I. Introduction

The dynamic behavior of viscoelastic plates is of primary importance in engineering applications. Adopting elastic theory to simplify the analysis proves to be inconsistent with reality since most engineering materials exhibit noticeable time effects due to internal friction. Therefore, viscoelastic constitutive relations should be employed instead of elastic constitutive relations to reflect the material behavior. There are many works in the literature on the theory of viscoelasticity [1-2]. For the problems that have complex geometries and constitutive relations, closed form solutions are often not possible and numerical solution methods should be employed. The application of Finite Element Method (FEM) to viscoelastic plate problems has been presented by number of authors [3-6]. When employing the conventional FEM, shear locking is an undesirable phenomenon. Considering suitable mixed finite element methods is a more general way for the prevention of shear locking phenomena. When formulating mixed type finite elements the Hellinger Reissner and the Hu-Washizu variational principles are more popular. However, in this study, the Gâteaux Differential Method, which is more powerful and efficient variational tool when compared to the Hellinger Reissner and the Hu-Washizu variational principles, is used to obtain a functional for the dynamic behaviour of viscoelastic Kirchhoff plates in Laplace-Carson space.

Based on the Gâteaux differential method, Aköz and his co-workers [7-11] analysed the quasi-static and dynamic behaviour of the viscoelastic beam and plate elements by employing the Kelvin and/or Three-parameter Kelvin model. In the solutions, the four parameter Kelvin solid model is employed. The performance of the method is presented by several dynamic example problems.

II. Field Equations and Functional

Classical thin plate theory neglects the transverse shear effects and field equations for viscoelastic Kirchhoff plates in Laplace-Carson space are given in (1). For more information, the reader is referred to the study of Aköz et al. [11].

\[
\begin{align*}
- \frac{\partial^2 M_x}{\partial x^2} - \frac{\partial^2 M_y}{\partial y^2} - 2 \frac{\partial^2 M_{xy}}{\partial x \partial y} &= \bar{q} \\
- \bar{M}_x - \bar{D} \left( \frac{\partial^2 \bar{w}}{\partial x^2} + \nu \frac{\partial^2 \bar{w}}{\partial y^2} \right) &= 0 \\
- \bar{M}_y - \bar{D} \left( \frac{\partial^2 \bar{w}}{\partial y^2} + \nu \frac{\partial^2 \bar{w}}{\partial x^2} \right) &= 0 \\
- \bar{M}_{xy} - (1 - \nu) \bar{D} \left( \frac{\partial^2 \bar{w}}{\partial x \partial y} \right) &= 0
\end{align*}
\]

where \( \bar{q} \) represents the normal load distribution in the Laplace-Carson domain, \( \bar{M}_x \), \( \bar{M}_y \), and \( \bar{M}_{xy} \) represents the moment resultants in the same space. Positive directions of the stress resultants are shown in Fig. 1. In addition, \( \bar{w} \) is the transverse displacement of the plate’s middle surface in the Laplace-Carson domain, \( \nu \) is the Poisson’s ratio and \( \bar{D} \) is the operator form of the flexural rigidity of the plate and it is related with the creep function \( \overline{\mathcal{P}} \) as follows:

\[
\bar{D} = \frac{h^3}{12} \overline{\mathcal{P}}
\]

where \( h \) is the thickness of the plate.
The boundary conditions in the Laplace-Carson space can be written in symbolic form as below:

\[ \overline{\mathbf{\tau}} - \hat{\mathbf{\tau}} = 0 \]
\[ -\overline{\mathbf{M}} + \hat{\mathbf{M}} = 0 \]

Equation (3) and (4) represent the dynamic and geometric boundary conditions, respectively.

Field equations can be written in operator form as:

\[ \overline{\mathbf{a}} = \mathbf{L} \overline{\mathbf{y}} - \hat{\mathbf{f}} \]  

where \( \overline{\mathbf{a}} \) is a potential operator if the equality

\[ < \mathbf{d} \overline{\mathbf{a}}(\overline{\mathbf{y}}, \overline{\mathbf{y}}'), \overline{\mathbf{y}}^* > = < \mathbf{d} \overline{\mathbf{a}}(\overline{\mathbf{y}}, \overline{\mathbf{y}}^*), \overline{\mathbf{y}}' > \]

is satisfied \[12\], where \( \mathbf{d} \overline{\mathbf{a}}(\overline{\mathbf{y}}, \overline{\mathbf{y}}') \) and \( \mathbf{d} \overline{\mathbf{a}}(\overline{\mathbf{y}}, \overline{\mathbf{y}}^* \) are the Gâteaux derivatives of the operator \( \overline{\mathbf{a}} \) and the parenthesis indicate the inner products.

The Gâteaux derivative of an operator is defined as:

\[ \mathbf{d} \overline{\mathbf{a}}(\overline{\mathbf{y}} - \overline{\mathbf{y}}') = \left. \frac{\partial \overline{\mathbf{a}}(\overline{\mathbf{y}} + \tau \overline{\mathbf{y}}')}{\partial \tau} \right|_{\tau = 0} \]

where \( \tau \) is a scalar quantity. After satisfying the requirement, the functional is obtained as:

\[ I(\overline{\mathbf{y}}) = \int_0^1 < \mathbf{\overline{a}}(s \overline{\mathbf{y}}, \overline{\mathbf{f}}), \overline{\mathbf{y}} > ds \]

where \( s \) is a scalar quantity. The explicit form of the functional corresponding to the field equations of the viscoelastic Kirchhoff plates in the Laplace-Carson domain becomes:
Hence, the relaxation modulus will be

$$J(t) = \frac{1}{E_1} \left( 1 - e^{\frac{E_1}{\eta} t} \right) + \frac{1}{E_2} \left( 1 - e^{\frac{E_2}{\eta} t} \right)$$

(11)

Example 1:

In this example, a simply-supported viscoelastic plate subjected to rectangular impulsive load for $t_1 = 10$ s (Type I) is considered. For the numerical inversion, MDOP, Dubner & Abate’s and Durbin’s methods are employed. The material density $\rho$ is assumed to be 200 kg/m$^3$ for the dynamic response. The central displacement and bending moment-time variations are presented in Fig. 6 for Dubner & Abate’s and Durbin’s methods. Fluctuation is observed in the MDOP inverse transform method for the time-dependent bending moment values at the center of the plate as time increases. In addition, the dynamic behavior of the viscoelastic plate will eventually disappear with time as expected.

Example 2:

In this example, the effect of the damping ratio $(E/\eta)$ in the dynamic behavior of a simply-supported viscoelastic thin plate is considered. The material density $\rho$ is assumed to be 200 kg/m$^3$ for the dynamic response. Durbin’s inverse transform method’ results are presented in Fig. 7 for triangular impulsive load (Type II) for $t_1= 10$ s. As expected, the vibration behavior of the viscoelastic plate resembles the vibration of an elastic plate for small values of viscosity coefficient.

Dr. Kadioğlu received his BSc, MSc and PhD from Istanbul Technical
University, Istanbul, Turkey. He is currently working as an Associate
Prof. in the Department of Civil Engineering at Istanbul Technical
University. He published over 35 papers in international journals and
conferences, 5 books and book chapters in the fields of Structural
Mechanics. Dr. Kadioğlu’s current research interests include: Composite
Structures, Stability of Structures and Vibration, Elastic, Viscoelastic
Analysis, Structural Analysis and Finite Element Methods.

Gülçin Tekin received her BSc degree in Civil Engineering from Yıldız
Technical University, Istanbul, Turkey. She completed MSc degree at
the Bogaziçi University, Istanbul, Turkey. She is currently a third-year
PhD student in the department of Civil Engineering at the Istanbul Technical
University, Istanbul, Turkey. Presently she is working as a research assistant
at Istanbul Technical University. Her areas of interest are Structural
Analysis, Mixed Finite Element Methods.
